TECHNICAL MEMORANDUM 78150

## EFFECT OF SHELF AGING ON O-RING MATERIALS

### SUMMARY

The physical properties of 13 commercial O-ring compounds after 7 and 12 years of shelf aging were compared with the original properties. No gross property changes were detected. All O-rings tested are considered suitable for use after 12 years of shelf aging.

### INTRODUCTION

The complexity, cost, and the possible disastrous consequence of the failure of any single component of a space vehicle have resulted in extreme reliability requirements for all components used in these vehicles. Because elastomeric materials are considered to be relatively perishable, much time and effort have been expended in developing specific, conclusive information on the effect of age on these materials. Described here are the results to date of one such effort.

### EXPERIMENTAL

In 1962, 300 O-rings made from each of 13 different compounds in size 2-220 were purchased from Parker Seal Company for use in compatibility studies. All O-rings were individually packaged in sealed envelopes. All O-rings of a given compound were made from the same batch of mixed stock. All O-rings were cured in the fourth quarter of 1962. In the first quarter of 1963, 10 O-rings of each compound were randomly selected for test. The cross section of each O-ring was measured in 10 places around the circumference of the O-ring with the average of the 100 measurements made on O-rings from each compound being used as a standard dimension for all O-rings of that batch.

Tensile strength and elongation were measured on these O-rings for use as baseline data in future studies. The remaining O-rings were stored in their original packages in an internal store room. The temperature varied over the range of 15° to 32°C (60° to 90°F), depending upon the season.

In the third quarter of 1969 and 1974, 7 and 12 years after the original physical property measurements were made, 20 O-rings for each test period were randomly selected from each compound. Ten of these were used for tensile strength and elongation measurements. The remaining 10 were used for hardness and compression deflection measurements. These last two parameters were not measured in the original tests but were measured in 1969 and 1974. The tensile, elongation, and hardness data are shown in the Table. The compression deflection data are shown in Figures 1 through 13.

## CONCLUSIONS

Based upon the results of this study and upon a visual examination of the O-rings tested, it is concluded that all the O-ring compounds tested are suitable for use after 12 years of shelf aging under the conditions described. Even though there are some changes in elongation with age, this property is of no real significance in O-rings, and applicable O-ring material specifications do not include elongation as a requirement. The differences in compression deflection characteristics are no greater than those normally found between different lots of O-rings made from the same compound.

TABLE. PHYSICAL PROPERTIES OF THIRTEEN O-RING COMPOUNDS
